# Estimating the causal effect Synthetic control method

## "arguably the most important innovation in the policy evaluation literature in the last 15 years"

Athey, S., & Imbens, G. W. (2017). The state of applied econometrics: Causality and policy evaluation. Journal of Economic perspectives, 31(2), 3-32.

### In this part

- Introducing the synthetic control method
- How to quantify uncertainty
- What choices do we need to make and how do these impact our causal effect estimates?
- Performing the synthetic control method with tidysynth package

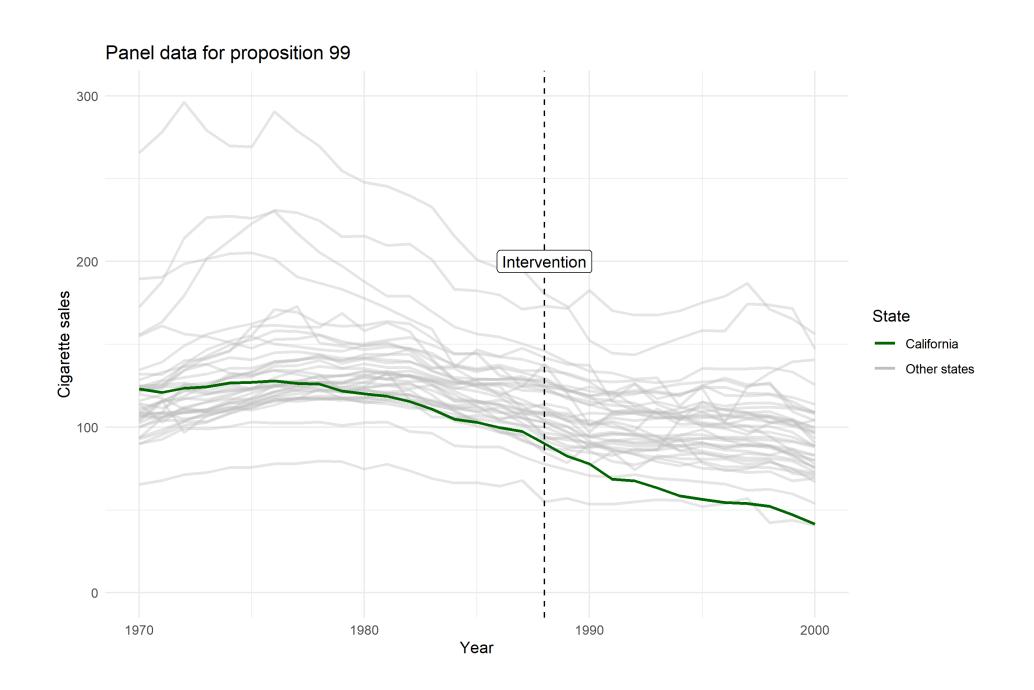

### **Basic idea**

With diff-in-diff we used a control unit to attempt a correction for unmeasured time-varying confounders (e.g., macroeconomic situation in U.S.A.)

- You need a good control unit!
- How much is Utah like California?

We can instead use a weighted average of a **donor pool** of control units to create a **synthetic control** unit

• Choose the weights such that control is like California

#### **Introduced in 2000s**

- Abadie, A., & Gardeazabal, J. (2003). The economic costs of conflict: A case study of the Basque Country. American Economic Review, 93(1), 113-132.
- Abadie, A., Diamond, A., & Hainmueller, J. (2010). Synthetic control methods for comparative case studies: Estimating the effect of California's tobacco control program. Journal of the American Statistical Association, 105(490), 493-505.

#### An R package with JSS paper in 2011

• Abadie, A., Diamond, A., & Hainmueller, J. (2011). Synth: An R package for synthetic control methods in comparative case studies. Journal of Statistical Software, 42(13).

#### A great overview paper with recent learnings in 2021

• Abadie, A. (2021). Using synthetic controls: Feasibility, data requirements, and methodological aspects. Journal of Economic Literature, 59(2), 391-425.

Causal **estimand** is the effect of the intervention at time *t*:

$$CE_t = Y_t^1 - Y_t^0$$

where  $t > T_0$  (i.e., the post-intervention time period)

$$CE_t = Y_t^1 - Y_t^0$$

- Again,  $Y_t^1$  is observed the post-intervention time series for the treated unit
- But  $Y_t^0$  is an unobserved counterfactual what would have happened had the treated unit been untreated?

$$CE_t = Y_t^1 - Y_t^0$$

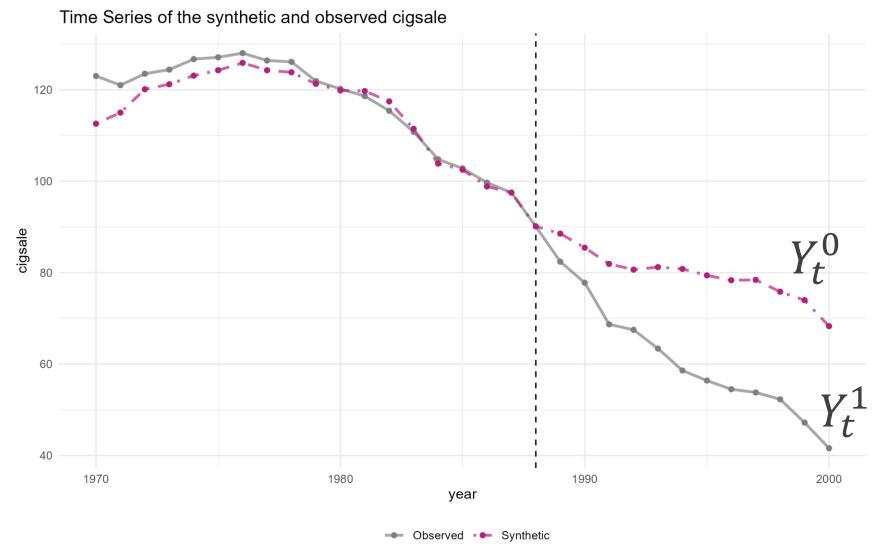

The problem of estimating the effect of a policy intervention is equivalent to the problem of estimating  $Y_t^0$ 

Abadie, A. (2021). Using synthetic controls: Feasibility, data requirements, and methodological aspects. Journal of Economic Literature, 59(2), 391-425.

We can estimate the counterfactual as follows:

$$Y_t^0 = \sum_{j=1}^J w_j C_{jt}$$

- $C_{jt}$  is the time-series for donor pool unit j at time t e.g., cigarette sales in Utah in 1989-2000
- $w_j$  is a weight for this state e.g., a single value like 0.334

### Three questions

- How to choose the weights?
- Which units can go in the donor pool?
- How to make sure that the synthetic control is interpretable?

- Choose weights such that the synthetic control looks like the treated unit
- Use only pre-intervention data for this
- Weights should be positive and sum to one Interpolation constraint / convex hull

What does it mean to looks like California? This is a choice by the researcher!

- Pre-intervention target variables
  - Cigarette sales
- Pre-intervention covariates
  - Population composition
  - Average income of population
  - Price of cigarettes
  - Beer consumption

- Simultaneous estimation of two weights
  - Unit weights  $w_j$ How important is each donor pool unit j?
  - Variable weights  $v_h$ How important is each variable p?
- Choose w to minimize v-weighed multivariate Euclidean distance between treated and synthetic control preintervention

$$\widehat{w}_j = \min_{w_j} ||v \cdot (X_T - w^T X_D)||$$

• Like nearest neighbours matching!

How to choose  $v_h$ ?

### **Simple**

Use inverse of variance of each variable *h*Like scaling the variables and then using unweighted Euclidean distance matching

#### **Complex**

Choose v such that root mean squared prediction error (RMSPE) on pre-intervention target variable is minimized Increased importance of good prediction. We will get back to this later

## Choosing donor pool

### No interference / spillover

The donor pool unit does not receive any intervention effect

### Example spillover effects

- Californians living near the border may buy their cigarettes in states across the border
- Other states may pass laws similar to on California

### Measurement

Measure control variables and target variable in the donor pool unit **before and after** the intervention

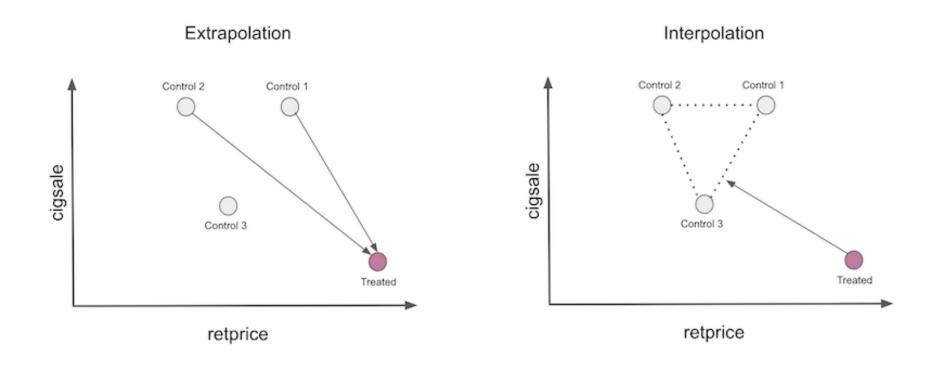

- Ideally, large pre-intervention time window Otherwise, risk overfitting pre-intervention; bad prediction for counterfactual
- Be able to measure target variable after intervention counterfactual is weighted average of this

### **Convex hull condition**

## Distribution of control and target variables in donor pool should cover treated unit

- It should be possible to interpolate the target unit values pre-intervention using the donor pool units
- If donor pool units all have much higher cigarette sales, it is impossible to represent cigarette sales in California using positive weights which sum to 1

### Interpolation

Alves, M. F. (2022). Causal inference for the brave and true.

## Interpretability

### Interpretability

- If donor pool is large, synthetic control can be combination of many units
- Hard to interpret what the synthetic control unit is!
- Therefore: sparse estimation of weights
- Additional penalty such that most weights are 0
- The units belonging to nonzero weights can be manually inspected

### Synthetic control using tidysynth

### Synthetic control in practice

```
library(tidyverse)
    library(tidysynth)
   # Read the dataset
    prop99 ← read_rds("data/proposition99.rds")
 6
    # Create synthetic control object
    prop99_syn ←
      prop99 ▷
      synthetic_control(
10
        outcome = cigsale,
11
12
        unit = state,
        time = year,
13
        i unit = "California",
14
        i time = 1988
15
16
```

```
# Now, generate the aggregate predictors used to estimate
38 # the weights
39
    prop99_syn ←
40
      prop99_syn ▷
     generate predictor(
41
        time_window = 1980:1988,
42
       lnincome = mean(lnincome, na.rm = TRUE),
43
        retprice = mean(retprice, na.rm = TRUE),
44
        age15to24 = mean(age15to24, na.rm = TRUE)
45
46
      ) >
47
48
       time window = 1984:1988,
49
        beer = mean(beer, na.rm = TRUE)
50
51
     generate predictor(
52
     time window = 1975,
53
        cigsale 1975 = cigsale
54
55
56
        time window = 1980,
        cigsale 1980 = cigsale
57
58
59
60
        time window = 1988,
        cigsale 1988 = cigsale
61
62
```

### Inspecting predictors

```
grab_predictors(prop99_syn)

 ... with 21 more rows
 i Use `print(n = ...)` to see more rows
```

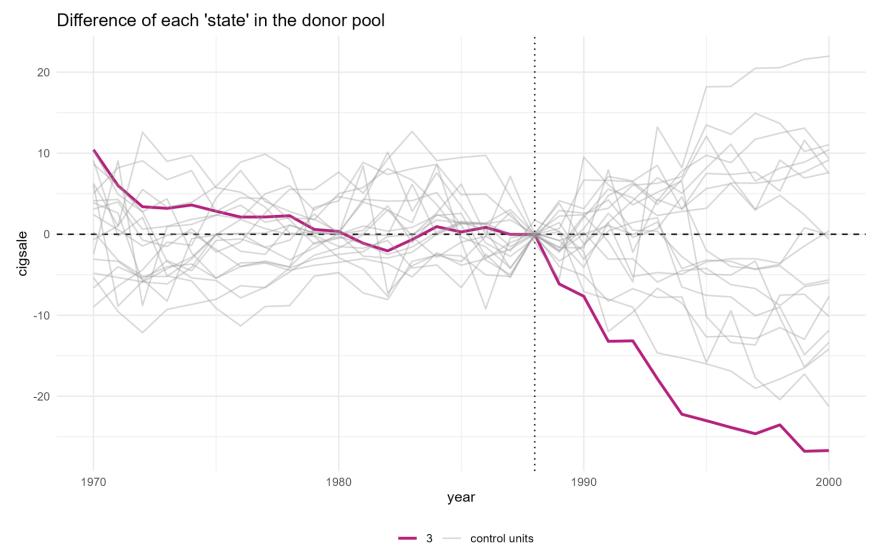

### Inference

### How to quantify uncertainty?

- Most common method: permutation test
- Apply synthetic control method many times, once for each unit in the donor pool
- These units have no intervention effect
- Create reference/null distribution of  $Y_t^0$
- Compare target unit's counterfactual to reference distribution
- Obtain a permutation p-value

Pruned all placebo cases with a pre-period RMSPE exceeding two times the treated unit's pre-period RMSPE.

## Choices, choices ...

### There are many choices

- Which units in the donor pool?
- Which control variables?
- What should my weights optimize?
- How many nonzero unit weights should I get?
- What settings do I give to the nonlinear optimizer?

"researcher degrees of freedom"

### There are many choices

- These choices influence your causal estimate  $\widehat{CE}_t$
- Make good choices ©
- Think of your causal estimate as "conditional" on the "model" (choices)
- Investigate the impact of different choices through robustness checks / sensitivity analysis

### Leave-one-unit-out validation

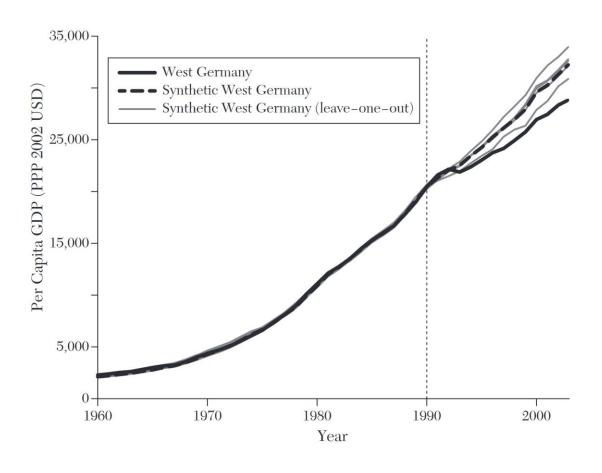

Figure 4. Leave-one-out Estimates of the Effect of the 1990 German Reunification

## More of this in the practical

# Practical: tidysynth, inference, robustness
